

(a) AIC selection frequencies
 $d = +12.5$: five clock standard errors

(b) Ideal precision needed for shape

King + clock, with Keck/VLT offsets and a fixed Planck-time reference scale. Panel (a): 20,000 synthetic repetitions per row.

Near-collinear histories; winner frequencies are not evidence probabilities. A selected candidate is not an amplitude detection.

Panel (b): refit amplitude and offsets for each alternative ($s = 1$ or 3); clock precision is unchanged. All astronomical errors scale ideally.

The reference levels 1 and 9 are residual-size benchmarks, not discovery significances. This is not an instrument forecast.
